Orientation and chain relaxation of amorphous polymers and compatible polymer blends. The change of the molecular weight between entanglements in the blend relatively to the pure components cannot account for the results. On the contrary, the increase in the mean friction coefficient in the blend, resulting from the interactions between the polymers leading to compatibility, appears as a major factor.

In the guidance of these theoretical considerations, we review recent progress toward dielectric polymers based on two major approaches, in terms of macromolecular architectures, namely main-chain and side-chain dielectric polymers, and various chemistry and compositions are discussed within each approach.

Dipolar glass (DG) polymers, which utilize sub-T<sub>g</sub> orientational polarization (T<sub>g</sub> is the glass transition temperature) to enhance dielectric constants, are promising candidates for use in advanced electronic and power applications because conduction of space charges (electrons and impurity ions) is suppressed in the glassy state, and thus, the dielectric loss is low.
